

Executive Summary: Status of Operations, Maintenance and Remedial Actions

September 29, 2023

INTRODUCTION

Since the last report six months ago, the City and County of Denver, Waste Management of Colorado, Inc., and Chemical Waste Management Inc., collectively referred to as the Work Settling Defendants (WSDs) conducted routine operations and maintenance (O&M) activities at and north of the Superfund Site. Details of the O&M activities are presented in this Status Report.

In summary, they consisted of extracting and treating approximately 8.7 million gallons of groundwater from several onsite and offsite extraction systems in full compliance with the Industrial Discharge Permit from Metro Water Recovery; collection and analyses of 138 samples from 77 groundwater monitoring wells; continuous operations of the Landfill Gas Extraction and Treatment system in full compliance with decision documents; collection of 21 landfill gas monitoring point samples for volatile organic compounds in compliance with decision documents; collection and analyses of soil gas samples from 64 subsurface gas monitoring probes surrounding the Lowry Landfill; collection and analysis of one stormwater sample; maintenance of stormwater conveyance ditches; and inspection and maintenance of landfill covers and buffer properties contiguous to the Superfund Site.

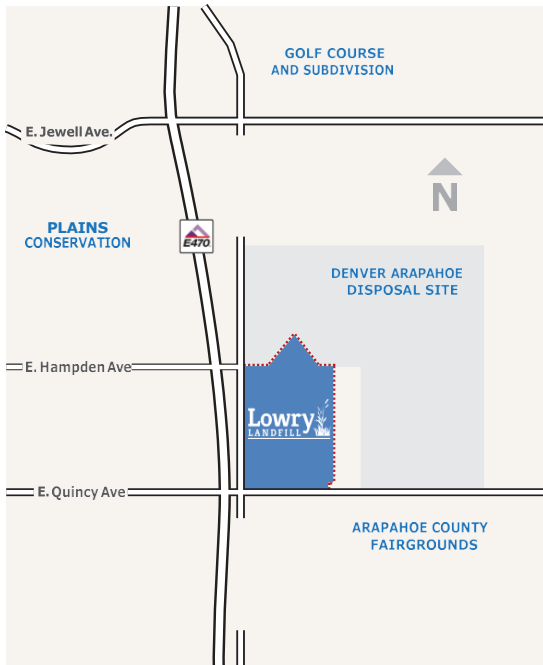

The area around the site consists of ongoing landfilling operations as well as residential and commercial areas. While monitoring and other operations and maintenance activities are ongoing, institutional controls, including deed restrictions, water rights, zoning, and ordinances ensure nearby residential areas are not impacted by the site contamination.

As part of the WSDs ongoing commitment to transparency and community engagement, all of site monitoring data generated during site operations and maintenance is shared on three websites maintained by USEPA, CDPHE, and the WSDs. Current and past documents, videos, presentations, and other content are available for all interested parties to download and review as desired. The WSDs will continue to provide updates on activities at the Site on publicly available websites, and opportunities for community involvement will continue to be provided through USEPA's public outreach coordinator.

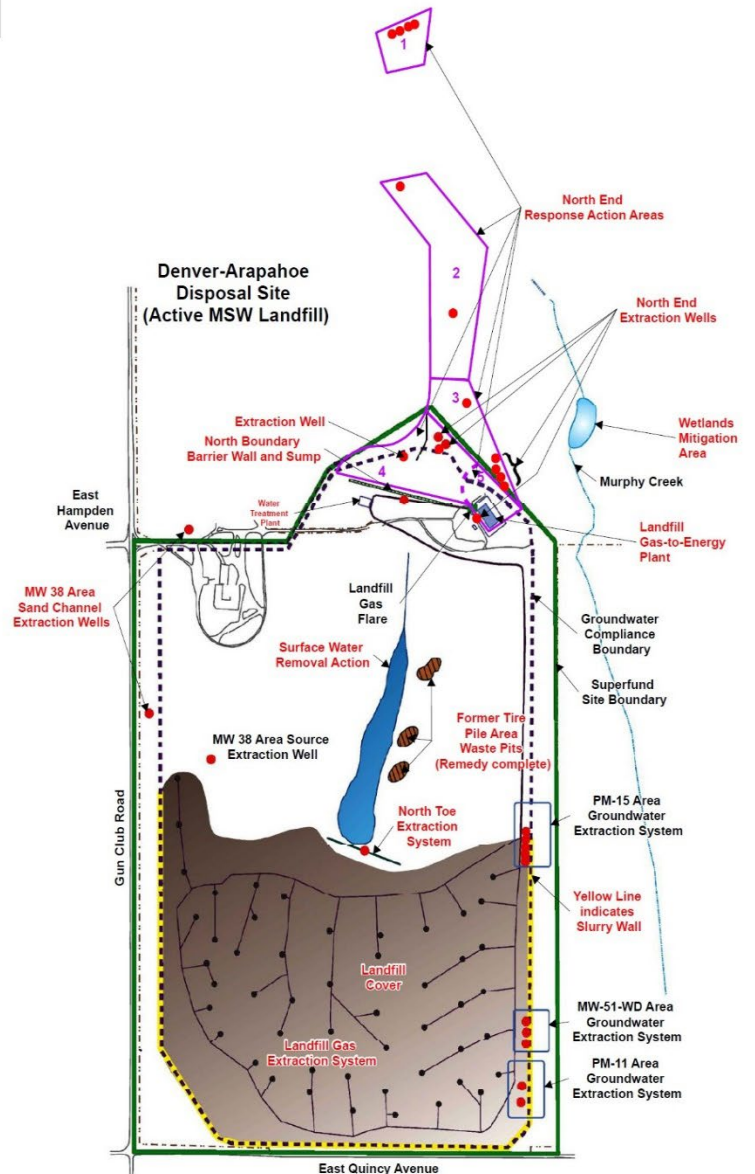

Conclusions from the Fifth Five Year Review for Lowry

In its Fifth Five Year Review (2022), the EPA concluded that the remedy at the Site is protective of human health and the environment. The following are specific areas of study that informed that determination.

LOCATION & CONTAINMENT REMEDY MAPS

Lowry Landfill Superfund Site Containment Remedy Components

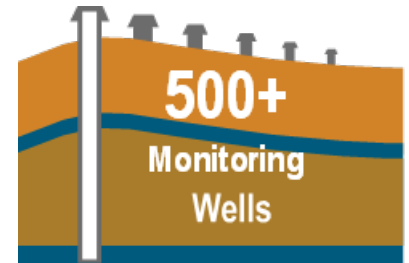

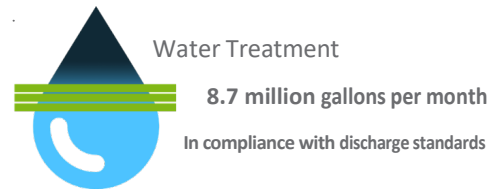

GROUNDWATER MONITORING

More than 500 monitoring wells extending into both shallow and deep aquifers have been installed within and outside the site to ensure that environmental resources and the community continues to be protected. Well and infrastructure inspections are a routine and critical part of the Lowry monitoring program and are conducted daily. Data shows that the monitoring system continues to be effective.

Groundwater remedy component effectiveness evaluations conducted in 2021 as part of the fourth five-year review determined that the remedial components are effective and achieve objectives. Specifically, the slurry wall – a vertical barrier wall made of clay that prevents groundwater flow – continues to effectively contain contamination inside the eastern, southern and western limits of the landfill as designed. The North Toe Extraction System, which collects and pumps water to the treatment plant at less than 0.5 gallon per minute, continues to capture the most contaminated groundwater emanating from the landfill. The 960-foot long North Boundary Barrier Wall (NBBW) located at the north end of the site is the most significant groundwater extraction feature, removing 6 to 10 gallons per minute, which prevents contamination from migrating offsite. Finally, groundwater extraction in the northwest corner of the site, known as the MW38 area, captures contaminated groundwater flowing through this area and prevents offsite migration.

Vertical migration monitoring shows vertical migration wells are in compliance with groundwater performance standards and that contaminated groundwater has not migrated to the deeper aquifers.

SITE CROSS SECTION

1,4-dioxane

- Synthetic industrial chemical sometimes added to solvents to prolong their useful life
- Used in some consumer products such as cosmetics, deodorants, soaps, toothpaste, anti-freeze & paint
- Site groundwater standard = 0.9 ppb

There are 60 compliance wells in the network, which are monitored for 29 different chemicals. There are 52 wells in compliance or potentially in compliance, and 8 wells are out of compliance, potentially out of compliance, or indeterminate for chemicals such as 1,4-dioxane, PCE, nitrate, nitrite, TCE, bromodichloromethane, and chloroform. The 8 wells that are out of, or potentially out of, compliance are being addressed by continuing to pump contaminated water to the treatment plant and monitoring, as discussed above. This method has proven to be effective at stopping groundwater flow in these areas and reducing chemical concentrations.

FACTORS AFFECTING CONTAMINANTS IN GROUNDWATER

1,4-dioxane and the North End

In 2005, the Colorado Water Quality Control Commission established a new groundwater standard for 1,4-dioxane. At that time, new technological advancements capable of detecting and measuring 1,4-dioxane at the new standards found 1,4-dioxane north of the site. That standard has been revised over the past 13 years, and the current state standard is now 0.35 parts per billion (ppb). Currently, the best available analytical technology is not able to reliably detect 1,4-dioxane at this concentration in site groundwater so a site-specific standard for Lowry Landfill is set at 0.9 ppb. The WSDs conduct project quantitation limit studies yearly to assess the industry's ability to detect 1,4-dioxane at lower concentrations and either confirm that 0.9 ppb remains appropriate or determine if a lower site-specific standard can be achieved.

Numerous response actions have been implemented that have effectively reduced the extent of 1,4-dioxane in the North End Area, and Compliance with discharge standards. There is a comprehensive monitoring program in place. Of the 37 current North End monitoring wells where trend analysis was performed, 89% are decreasing and 11% have no trend (i.e., are not increasing or decreasing). The observed concentration declines in all areas shows the effectiveness of the ongoing response actions and demonstrates that groundwater quality in this area is improving. Data shows that the groundwater extraction response at the site continues to significantly reduce the 1,4-dioxane concentrations, as well as the width and length of the 1,4-dioxane plume north of the site. An animation of the North End plume over time is available at www.lowrylandfillinfo.com. As stated in the 2022 Five-Year Review, "Based on the results of the North End investigation, groundwater contamination from the Site is not affecting these residential areas." Furthermore, the report states, "There are no complete exposure pathways from 1,4-dioxane in shallow groundwater. Monitoring results indicate concentrations are decreasing or stable in most off-site wells. Monitoring and extraction will continue to reduce 1,4-dioxane concentrations and prevent further migration of the plume to the north."

MW38 Sand Channel

Remedial actions to contain groundwater and reduce contaminant concentrations in the MW38 sand channel have also been successful. Water is pumped out of the sand channel to maintain inward

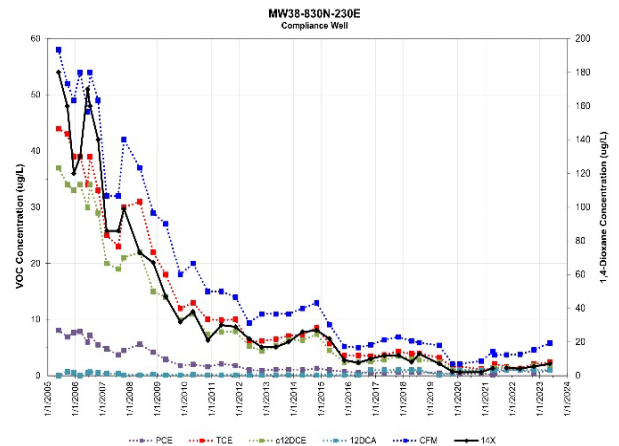

groundwater flow ensuring the surrounding groundwater is always flowing inward, and to prevent offsite migration of contaminants. The extracted water is sent to the treatment plant for treatment and disposal. Levels of 1,4-dioxane have been reduced by 96.1% since pumping began in this area in May 2005. Chloroform and trichloroethene concentrations have also been reduced by 90% and 95%, respectively. See graph at right.

Nitrate in the NBBW Area

One well is exceeding the nitrite and nitrate standards in an area where sewage sludge was historically land farmed to cultivate and enhance microbial degradation of the sludge. This well is located along the northern boundary of the Site. There does not appear to be a potential for significant off-Site migration of nitrate or nitrite at concentrations greater than the performance standard and monitoring is ongoing. Additionally, groundwater extraction from the North End wells further downgradient would capture any potential migration of these compounds if it were to occur.

WATER TREATMENT PLANT

The water treatment plant uses a natural biological process and advanced oxidation treatment to destroy more than 92% of the organic compounds coming into the plant. An ion-exchange system is used to reduce molybdenum by an average of 97%. The pretreated water is then discharged to a publicly owned wastewater treatment plant for further treatment. The on-site treatment plant removes all site chemicals to safe standards and leaves a minimal environmental footprint. It treats approximately 8.7 million gallons of contaminated groundwater every month. The data show the plant continues to operate as designed in compliance with discharge standards.

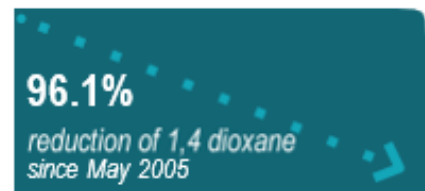

At Lowry

Extraction and treatment continue to decrease concentrations.

North End Area: 37 Wells

MW38 Channel:

LANDFILL GAS REMEDY

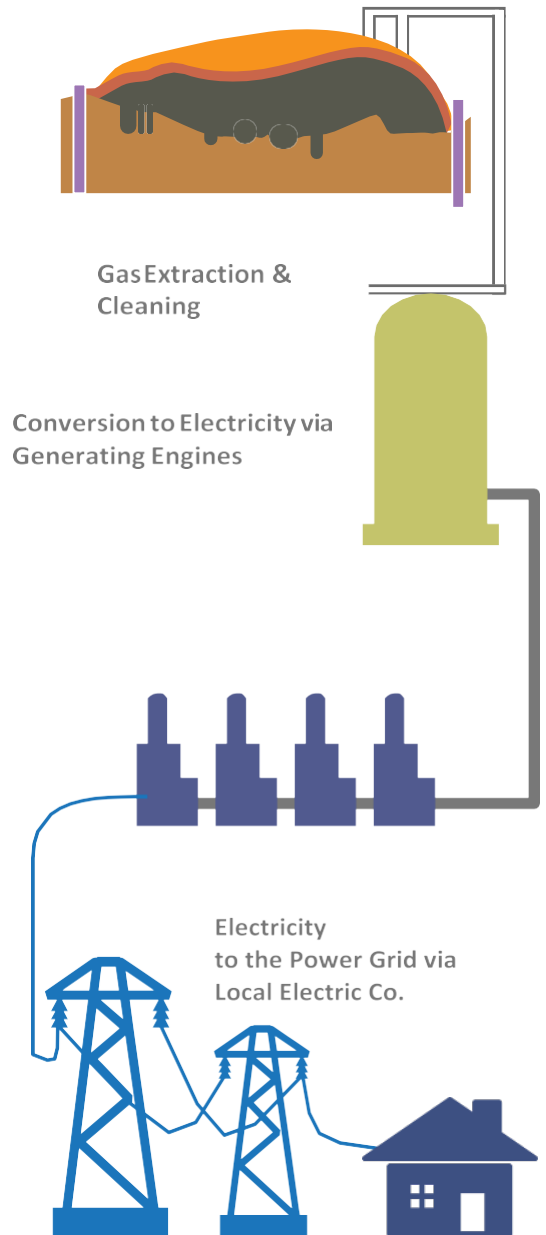

Landfill gas—made up of methane, carbon dioxide, nitrogen and other gases—is created naturally by the biological decomposition of organic matter in landfills under low-oxygen conditions. The generation of landfill gas is an indication that waste disposed of in the landfill are degrading. The Site’s landfill gas extraction, collection and treatment system continues to be effective and in compliance, including the gas-to-energy treatment plant, which removes roughly 5,000 tons of methane annually. This equates to removing more than 22,000 cars from the road each year. The on-site power plant, constructed in 2008, uses landfill gas to fuel four internal combustion engines that generate electricity for a local utility company. The electrical power generated is enough to supply 2,500 to 3,000 households.

LANDFILL COVER

The former landfill is covered by 4 to 12 feet of compacted clay and soil. The “cap” reduces infiltration of rain and snow into the soil, which minimizes further groundwater contamination. The cover continues to effectively drain rain and snow, keeping it from penetrating the soil. The cap is routinely monitored for any depressions that may form due to settlement that would cause rainwater to pond, among other issues. No cap settlement issues were identified in this report.

Gas to Energy Process
